Using MDT to Deploy Windows Server 2016

From the reference computer, LON-SVR1, the deployment share should be configured from the Domain Controller. The target computer does not have an operating system and will be used as a test by creating a reference image of Windows Server 2016, which is deployed at the end of the lab. The image from the reference computer is a thin image, which contains only the operating system and a few agents.

Once the deployment share adds to the Deployment Workbench in MDT, a reference image of Windows Server 2016 and Excel Viewer application are added from a DVD drive. Then, the deployment task sequence gets set up and shared with the reference computer. The target computer also gets LiteTouch software from the DVD drive. It only provides a limited OS so that the computer can run at least. Finally, the administrator deploys the image and application via MDT to the target computer, LON-SVR6. If this task sequence works as planned, it can be deployed to other computers.
